(57)ABSTRACT

An adjustable stair stringer and railing construction assembly is disclosed. The assembly is adapted to use a pair of parallel stringer arms for each side of the stair, a riser/tred support bracket for each stair, and alignment and spacing elements for spacing the support brackets along the stringers. The brackets include formations for spacing the stringers with respect to each other and for spacing adjacent brackets along the stringers. The brackets are initially pivotally attached to each of the stringers so as to be rotatably movable about their pivotal attachment as the stringers are moved axially. Axial movement of the stringers with respect to each other establishes the angle of rise of the stair. Treds and risers are attached to the brackets to form the stairs and railings are attachable to the stringer and bracket assembly to complete the construction.

ADJUSTABLE STAIR STRINGER AND RAILING

This application claims priority from Provisional Application No. 60/085,151 for ADJUSTABLE STAIR STRINGER AND RAILING filed May 21, 1998 by Richard Truckner and Paul Truckner.

Numerous innovations for adjustable stairways have been provided in the prior art that are described as follows. Even though these innovations may be suitable for specific 10 individual purposes to which they address, they differ from the present invention as hereinafter contrasted.

The prior art does not utilize a pivoted motion and does not allow an infinite amount of variable spacings when framing stairs and/or a railing. The present invention allows 15 an infinite amount of variable spacings and use of a pivoting motion.

U.S. Pat. No. 2,245,825 to W. E. Ross teaches a folding stand that has pivoting support but is not based on vertical holes which keep treds in a horizontal position with an ²⁰ infinite amount of variable spacings. Furthermore, the patented invention utilizes different elements from the present invention. Some of the differences are:

- 1) Vertical holes are not important,
- 2) Stair is adjustable into one position only,
- 3) Not meant to be permanently fixed after moved into position on risers,
- 4) Risers and treds to not slide past each other,
- 5) Pivoting tred support is not fixed in position after 30 adjustment and therefore not used to lock stringers.

U.S. Pat. No. 4,370,664 to J. J. Whitehead teaches an adjustable staircase. The patented invention does not have any pivoting motion and utilizes different elements from the present invention.

U.S. Pat. No. 3,885,365 to J. W. Cox teaches a self adjusting stair which utilizes a truss assemblage. In the patented invention adjustments are made using a pin and slot. The patented invention does not utilize any pivoting motion and the rails are not adjusted by stringers as with the present invention.

U.S. Pat. No. 3,962,838 to J. W. Cox teaches a self adjusting stair which utilizes spacers in a truss assemblage. The patented invention does not utilize a pivoting motion and the rails are not adjusted by stringers.

U.S. Pat. No. 4,406,347 to N. M. Strathopoulos teaches a modular staircase assembly. The patented invention does not utilize a pivoting motion. The rails are not adjusted by stringers and are not adjusted on vertical holes.

U.S. Pat. No. 4,959,935 to H. R. Stob teaches a prefabricated adjustable stairway. The patented invention does not utilize a pivoting motion and the rails are not adjusted by stringers. This apparatus uses a three point pivoting action so that stringers do not separate during adjustment and slide one on top of the other.

U.S. Pat. No. 5,189,854 to K. J. Nebel teaches an adjustable height staircase. The patented invention does not utilize a pivoting apparatus as described herein. The present invention utilizes a pivoting apparatus and contains different elements from the patented invention for at least the following reasons:

- 1) Treds are directly connected to stringers,
- 2) No risers,
- 3) No sliding motion of riser past the tred.

U.S. Pat. No. 4,124,957 to Pouplaw shows treds that are 65 directly connected to stringers, stringers that have special tongue and groove spacers which must be an exact size each

2

time in order to lock stringers otherwise the stringers must be secured top and botton of the stair only, and risers and treds do not slide past each other.

Numerous innovations for adjustable staircases have been provided in the prior art that are adapted to be used. Even though these innovations may be suitable for specific individual purposes to which they address, they would not be suitable for the purposes of the present invention as here-tofore described.

SUMMARY OF THE INVENTION

The structure of the present invention can be used for forming a stair and may also be used as a support for concrete form work, as a form for a ramp, as a form for adjustable shelves, as an adjustable bleacher, and for adjustable displays.

It is an object of the present invention to provide an adjustable stringer and railing that allows users to have a quickly formed stair structure.

It is another object of the present invention to provide an adjustable stringer and railing that provides partially assembled elements that can be adjusted to a variety of applications and then securely fixed to form a stair framing and/or railing framing.

It is another object of the present invention to provide an adjustable stringer and railing that utilizes a pivoting motion.

It is another object of the present invention to provide an adjustable stringer and railing that allows an infinite amount of variable spacings when creating stairs and/or railing.

It is another object of the present invention to provide an adjustable stringer and railing that eliminates the need to calculate spacing between step treds and angle of the stairs.

It is another object of the present invention to provide an adjustable stringer and railing that provides an embodiment that includes an upper stringer arm, a lower stringer arm and at least one riser support.

It is another object of the present invention to provide an adjustable stringer and railing that provides an embodiment that includes an upper rail support and at least two railing posts pivotally attached to the upper rail support.

It is another object of the present invention to provide an adjustable stringer and railing that is easy and inexpensive to manufacture.

Another object of the present invention is the use of a bracket and setting and spacer bar that can be used with stringer elements for simplifying the formation of a stair assembly with treds, risers and rail supports.

Further objects of the present invention include a stair forming apparatus that includes a pivoting block to which treds and risers can be attached, a pivoting block to which treds only can be attached, a pivoting block which allows risers and treds to slide past each other, a pivoting block which allows risers and treds to be attached such that the risers and treds can be attached to each other after assembly to form a solid construction in which the risers become beams and the treds become lateral bracing to produce great structural stength and much wider stair widths than normal with on center supports (additional stringers) as with normal stairs, and greater stringer strength than with normal saw tooth stringers because of greater stringer depth and, when the riser/tred supports are secured to the upper and lower stringers after adjustment, the stringers are bonded together to form one solid stringer which also is capable of much greater spans without additional supports.

3

The structure of the present invention includes riser and tred support which allows risers and tred to slide past each other (as the stinger is adjusted) in order to utilize standard lumber and eliminate the need to cut lumber to exact widths, to use standard lumber of varing lengths according to width of the stair (i.e. 4' to 10' wide stairs), to use riser and tred support systems which, after pivoting and adjusting in position, allows risers to be used as beams which greatly increases the structural strength of the stair allowing much greater stair widths than normal without the need for addi- 10 tional center support stringers, and provides a stringer system which, when the riser/tred supports are secured, the stringer members are bonded together to form a much stronger stringer member than in normal "saw tooth" type construction giving much greater stair lengths without addi- 15 of FIG. 27. tional supports.

The foregoing benefits are accomplished with the use of a simplified bracket, spacer and setting combination that permits the assembly of a stair stringer assembly without difficulty permitting the "do it your-selfer" to install a stair ²⁰ assembly with simple instructions.

BRIEF DESCRIPTION OF THE DRAWINGS

- FIG. 1 is a side view of the stair embodiment of the adjustable stair stringer and railing illustrating two possible inclinations.
- FIG. 2 is a side view of the railing embodiment of the adjustable stair stringer and railing.
- FIG. 3 is a top view of the adjustable stair stringer and $_{30}$ railing.
- FIG. 4 is a front view showing the assembled stair and railing set in position.
 - FIG. 5 is a side view showing the assembled stairs.
- FIG. $\bf 6$ is a side view of an alternative form of the 35 adjustable stair as assembled.
- FIG. 7 is a side view showing the adjustable stair in two alternative rise angles using the same elements.
- FIG. 8 is a perspective view showing the nailing block and pivot attachment plate for the stair assembly of FIG. 7.
- FIG. 9 is a perspective view of an alternative riser tred support.
- FIG. 10 is a perspective view of the attachment bracket as used in the present invention.
- FIG. 11 is a top plan view of a stair assembly of the form of FIG. 7 with risers and without the treds.
- FIG. 12 is a sectional view of a stair assembly of the form of FIG. 7 with the use of horizontal pivots.
- FIG. 13 is a perspective view of the tred support bracket 50 as used in FIG. 12.
- FIG. 14 is an alternative form of a tred support and riser support using horizontal pivots as used in FIG. 12.
- FIG. 15 is an elevation view showing alternative riser/tred supports which are individually set on a two piece stringer.
- FIG. 16 is an elevation view showing the riser/tred supports adjusted in position.
- FIG. 17 is a perspective view of the riser/tred support of FIGS. 15 & 16.
- FIG. 18 is an alternative form of the present invention using a single pivot point for a riser/tred support.
- FIGS. 19 & 20 are alternative forms of tred support and riser support for the assembly of FIG. 18.
- FIG. 21 is a side elevation view with an alternative stair 65 assembly showing riser/tred supports and setting spacing blocks.

4

- FIG. 22 is a partial top plan view of a portion of FIG. 21.
- FIG. 23 is a side elevation view of the alternative riser/ tred supports of FIG. 21 after removal of the setting/spacing blocks and as set for assembly as a stair riser and tred support.
- FIGS. **24** and **25** are perspective views of the riser/tred support and setting/spacing block after separation.
- FIG. 26 is a top plan view of a structure from which a bracket may be formed.
- FIG. 27 is a top plan view of a setting and spacer bar for use with the bracket of FIG. 26.
 - FIG. 28 is a side elevation view of FIG. 27.
- FIG. 29 is a sectional view taken along the lines 29—29 of FIG. 27.
- FIGS. 30, 31 and 32 are alternative forms of bracket elements with setting/spacing bars.
- FIG. **33** is a view showing alternative adjustable spacing constructins.
- FIGS. 34A, 34B, 35A, 35B, 36A and 36B illustrate the use of the brackets, setting/spacer bars and stringer elements of the present invention.
- FIGS. **37**, **38**A and **38**B are side elevation views of riser formwork and locking clamp using a two piece stinger and riser/formwork supports.

DETAILED DESCRIPTION OF EMBODIMENTS

Referring to FIG. 1 which is a side view of the stair embodiment of an adjustable stair stringer and railing 110 which includes an upper stringer arm 112, a lower stringer arm 114 and at least one riser/tred support 116. The upper stringer arm 112 is parallel to the lower stringer arm 114. The riser/tred support 116 is pivotally attached to the upper stringer arm 112 and pivotally attached to the lower stringer arm 114. The riser/tred support 116 may be attached to the upper stringer arm 112 and lower stringer arm 114 by riser/tred stringer arm fasteners 118. The riser/tred stringer arm fastener 118 can be a pin, screw, bolt, clamp, dowel or hook.

The riser/tred support 116 can be in the shape of a rectangle, square, triangle, pentangle or circle. The riser/tred support 116 may be rectangular in shape and contain a riser/tred support beveled corner 116A. Furthermore, if there are more than one riser/tred supports 116 the riser/tred supports 116 can be positioned equally along the upper stringer arm 112 and lower stringer arm 114. The riser/tred supports 116 can be attached at horizontally positioned fixed points 116B fastened to the upper stringer arm 112 and lower stringer arm 114.

The stair embodiment of the adjustable stair stringer and railing 110 can include a lower stringer support 120 which can be attachable to the upper stringer arm 112 and the lower stringer arm 114, and an upper stringer support 122 which can be attachable to the upper stringer arm 112 and the lower stringer arm 114.

The stair embodiment of the adjustable stair stringer and railing 110 can be manufactured from wood, fiberglass, metal, metal alloys, epoxy, carbon graphite, concrete or plastic. It further can be adapted for use to pour concrete and create concrete stairs.

The railing embodiment of the adjustable stair stringer and railing 210 as shown in FIG. 2 showing risers 80 and treds 90 contains an upper rail support 212 and at least two railing posts 214. The two railing posts 214 are pivotally attached to the upper rail support 212. The at least two

railing posts 214 are pivotally attached to the upper rail support 212 by upper rail support railing posts fasteners 218. The upper rail support railing post fastener 218 can be a pin, screw, bolt, clamp, dowel or a hook.

The railing embodiment of the adjustable stair stringer 5 and railing 210 can contain at least one banister 216 pivotally attachable and/or attached to the upper rail support 212. The at least one ballister 216 is parallel to the railing posts 214. The banister 216 can be attached to the upper rail support 212 by an upper rail support banister fastener 222. The at least one banister 216 can be positioned equally along the upper rail support 212. The upper rail support banister fastener 222 can be a pin, screw, bolt, clamp, dowel or hook.

The rail embodiment of the adjustable stair stringer and railing 210 can contain an upper rail support railing cap 212A which is attached to the upper rail support 212. It can further contain a railing post attachment 220 attachable to each of the railing posts 214.

It will be understood that each of the elements describe above, or two or more together, may also find useful application in other types of constructions differing from the type described above.

FIGS. 6-10 illustrate an alternative form of the stringer, In this form a two piece stringer 310A (lower) and 310B (upper), as shown in FIGS. 6 & 7, is first attached to a deck or wall vertical surface by an attachment bracket 312, as shown in FIG. 10, with the two pieces of the stringer attached to pivot holes 312A in the bracket. Riser/tred supports 314 having pivot holes 316 spaced the same distances as the pivot holes in the attachment bracket are spaced along the risers and are fixed to the risers by suitable means at screw holes 318 to cause the riser/tred supports to be parallel to the attachment bracket and equally spaced along the risers. These vertical pivot riser/tred support 314 are unique because the supports pivot for adjustment only and are fixed in position after adjustment; the fixing of the riser/tred supports joins the two pieces of the stringer to form a one piece, permanently adjusted stringer which is structurally superior to normal stair construction; the positioning of the pivot points (opposite risers) allows the top of the stair to be attached the same distance down from the deck/floor level each time regardless of the riser height because all tion of the riser/tred support allows risers 80 and treds 90 to slide against each other for adjustment; and when the risers are attached to the riser/tred supports and the treds, each riser then acts as a beam giving the stair much greater structural stability and allowing greater widths for a stair without additional supports. The riser/tred supports 314 can be constructed from metal, composites and other materials. It should be evident that the riser/tred supports 314 are now vertical if the surface of the deck where attachment was made was vertical when the attachment bracket was 55 attached, and as illustrated in the two positions shown in FIG. 7, the riser/tred supports are now in position to be permanently attached to the stringers at securing holes 318 and to have risers 80 and treds 90 attached to the supports.

FIGS. 12–14 illustrate an alternative form of the stringer, riser and tred assembly formed using horizontal pivoted tred support brackets and including an alternative tred support with riser support elements. FIG. 13 shows alternative pivoting tred supports using a straight bracket 412 and FIG. 14 another support 414, which is truncated in shape which 65 can be used with or without a riser, but allowing greater fixing to the stringer. Riser 80 and treds 90 can still slide past

each other to form beams. There are three steps shown on the drawing which illustrates how this system would be installed with pivot points that are horizontal.

The feature of the riser/tred support in either the vertical or horizontal pivoted form is that it is a one piece apparatus which attaches to the two piece stringer using two pivot points which normally are vertical or horizontal but can be at any common angle. The riser/tred supports pivots to adjust for a required height to form the correct stair profile. The riser/tred support is then fixed in position (using nails, screws, bolts, glue, etc.) against the two piece stringer to form one solid, non-moving stringer which is capable of supporting both risers and treds or treds alone or risers alone (when being used for concrete formwork). The two piece stringer is then cut (at the dotted lines shown) to conform to the deck or wall at the top and the base at ground level at the bottom. The riser/tred support allows risers and treds to slide past each other so that the risers can be adjusted for height sliding up or down past the back of the tred. The back of the tred is pushed against the face of the riser to form an enclosed stair. The position of the risers and treds can vary infinitely in respect to each other depending on the stair adjustment.

FIGS. 15-17 illustrate a further alternative form for riser and tred assembly in accord with the present invention. 25 riser/tred supports 512 which are individually set on a two piece stringer 310A and 310B using removable setting blocks 514 and setting pins 516. In this form the removable setting blocks 514 are used to space the riser/tred supports equally along the two piece stringer by being placed on a reference surface of a support and as their ends abut along the stringer. The stringer pieces are separated from each other by the removable setting pin 516 and the riser/tred supports 512 are attached at their pivot points 518A and 518B to the stringer 112 and to the stringer 114. When the setting blocks 514 and the setting pins 516 are removed, the two parts of the stringer can be slid with respect to each other to adjust the riser/tred supports 512 in the desired vertical position and the riser/tred supports can then be secured to the stringers by screws, nails, or other fasteners at securing holes 520. The riser/tred supports are then in position for the attachment of equally spaced treds and risers.

FIGS. 18–20 illustrate a stair section showing pivoting riser/tred supports using a single pivot point allowing the tred to be set level after stringer installation. Equally spaced risers adjust equally including the first riser; the configura- 45 support brackets 612 are pivoted at a single pivot 614 position of the stringer with those pivot positions being located the same distance below the deck/floor when the stringer is attached with the pivot position a desired distance below the level of the deck or floor to which the stair is to be attached. With a single pivot point for each of the equally spaced riser/tred supports, the supports can be attached to the second stringer by suitable means and the treds will always be equally spaced and will have equal rising distances. The single pivot point can be at any common point (shown as alternatives 614B) along the riser/tred support brackets 612 and the brackets can be just a tred support or a tred and riser support. FIG. 20 illustrates an alternative form 612B for the bracket in a truncated form.

> FIGS. 21–25 illustrate another alternative form for riser/ tred supports for use in the present invention. In this form the riser/tred supports 712 are individually set on a two piece stringer 112-114 using removable setting/spacing blocks 714. This form of two piece stringer/riser/tred support assembly can be assembled with the stringers 112-114 and the riser/tred supports 712 in place by attachment means at the pivots 712A and with the riser/tred supports spaced by the body 716 of setting/spacing blocks 714 mating and

7

cooperating extensions 718A and 718B with centering slots 720A and 720B in the riser/tred supports. When the assembly is to be used, 720A and 720B in the riser/tred supports. When the assembly is to be used, the setting/spacing blocks can then be removed from the riser/tred supports and the stringers can then slid with respect to each other to rotate the riser/tred supports about their pivot points. The stringer can then be attached to the face of the deck or wall where the stair is to be attached and the stringers can be cut (at possible cut lines shown) to face against the deck or wall. The riser/tred supports will then be equally spaced both vertically and horizontally, can be attached by suitable fastening means to the stringers, and are in position for installation of risers and treds.

FIGS. 26–33 illustrate another alternative form for a riser/tred support bracket 812. This form may be formed from a metal or other suitable material blank 812A with stamped holes, slots and side portions to from the bracket. The side protions 813 and 814 from the tred and riser support surfaces (respectively) with stamped holes 815 for attaching means for the treds and risers. Pivot holes 816 are used for connecting the bracket to the stringers and holes 817 are for fixing the bracket in place when a stringer assembly is completed. The bracket 812 is provided with stamped alignment guide holes at 819 and a guide slot at 820.

FIGS. 29–31 illustrate a setting and spacing bar 822. The setting and spacing bar may be formed of metal or other suitable material and includes a central body portion 823 with folded ears 824 at each side and with a guide tab 825 formed at each end of the body portion.

The setting and spacing bar 822 is adapted to cooperate with and space two brackets 812 by aligning the guide tab 825 with the guide hole 819 at one bracket and with guide slot 820 in the next bracket and serves to establish the spacing between brackets. The folded ears 824 separate two stringers and thus to allow for the space for relative movement between stringers.

With at least a pair of brackets **812** spaced by setting and spacing bars **822** and an upper and lower stringer the 40 brackets may be attached by suitable means to the stringers at the pivot holes **816** to provide aligned and spaced riser/tred brackets for a stair assembly as will be described with reference to FIGS. **34–38**.

FIGS. 30-33 illustrate alternative forms for riser/tred 45 brackets similar to that shown in FIGS. 26-29. FIG. 30 illustrates a bracket 812 with a setting and spacing bar 822 integrally formed with the bracket. The bar 822 has a length designed to space adjacent brackets and a near central folded ear portion 824 for spacing stringers. The bar 822 would be 50 detachable after it has functioned in setting and spacing. FIG. 31 illustrates another alternative of an integrally formed bracket 812 with a removable spacing bar 822 and a central setting body 824. FIG. 32 is another alternative bracket similar to FIG. 31 with a removable spacing bar 822 and a central plug 826 for spacing the stringers. FIG. 33 illustrates alternative forms for the end of a spacing bar 822 to adapt the bracket to different spacings of brackets along a stringer assembly. The spacing bar may include holes or pins at 822A or notches at 822B. Spacing bars of the type shown here can be used with the brackets 116 shown in FIG. 5 by cooperating with the spacer slots 115 in positioning brackets 116 before stringers 112 and 114 are moved relative to each other in setting the brackets 116 for receiving treds and/or risers.

FIGS. 34–36 illustrate the use of the brackets with stringers in the formation of a stair assembly. FIGS. 34A and 34B

8

illustrate the opposite sides of a stair stringer assembly, each side having an upper 112 and lower 114 stringer with a plurality of brackets 812 of the type illustrated in FIGS. 26–29 (or of the types shown in FIGS. 1–25) and employing setting and spacing bars 822 to position the brackets along the stringers. The two stringer assemblies mirror each other to be left and right sides of a stairway. When assembled, spaced and guided, the brackets are attached to the stringers by suitable means through pivot holes 316. FIGS. 35A and 35B illustrate the moved portion of the stringers 812–814 and the rotation of the brackets 812 to the deaired position for attachment to a deck or wall and for tred and riser attachment after cutting the stingers for attachment to the deck or wall. At this stage in the formation of the stringer assembly the brackets 812 can be permanently attached to the stringers at the provided attachment holes.

FIGS. 36A and 36B illustrate the completed stair using the brackets and movable stringers of the present invention. It should be noted that the forward holes 815 along the tred side portions 813 of the bracket of FIG. 26 premit the location for predrilling guide holes into a tred from below. By knocking the tred against the bracket, the raised holes will mark the underside of the tred. Predrilling guide holes will permit ease of assembly of the tred from below before a riser is added to the face of the stair.

FIGS. 37 and 38A illustrate the use of the principle of the present invention for the positioning of formwork for poured concrete stairs. The use of two part parallel stingers with pivoted riser/formwork supports permits the setting of equally spaced horizontal riser forms and equally spaced vertical spaces between poured stairs. The two piece stringer is first set at the desired angle and the separated stinger parts are fixed with respect to the top and bottom of the desired stair. Equally spaced riser/formwork supports are positioned along the risers by attachment at pivot points with the support elements having adjustment slots (FIG. 37) or by the use of locking holders (FIG. 38B). Riser formwork elements are attached to the free end of each of the supports. Concrete aggregate can then be poured behind each of the riser formworks to the desired level for the stairs and allowed to set. It should be evident that the face of the riser formwork elements can be adjusted to a desired angle other than vertical by adjusting the relative positions of the two stringer elements. The riser height adjustment can be achieved by setting the first and last support and their riser formworks in position and then raising or lowering intermediate supported riser formworks to a string line drawn from the first to the last support. Equally spaced horizontal supports will then result in equally spaced vertical riser formworks.

While certain preferred embodiments of the invention have been specifically disclosed, it should be understood that the invention is not limited thereto as many variations will be readily apparent to those skilled in the art and the invention is to be given its broadest possible interpertation within the terms of the following claims.

We claim:

1. A riser/tread support bracket and aligning/spacing means kit for use with duplicate kits in an adjustable stair assembly for at least one side of a stairway, said stair assembly having a pair of parallel stringers at said at least one side, a plurality of said support brackets adjacent to each other along said parallel stringers, and said aligning/spacing means of said kit being adapted for spacing and aligning said support bracket of said kit with respect to adjacent support brackets from said duplicate kits along said parallel stringers and for spacing said parallel stringers:

said support bracket of said kit comprising,

- a) a support bracket having a tread support surface and at least a reference surface having engagement means, and means for accommodating fastening means.
- b) said means for accomodating fastening means comprising a pair of holes in said support bracket, one of said pair of holes being adapted and aligned for pivotally attaching said support bracket to one of said spaced parallel stringers, the other of said pair of holes being adapted and aligned for pivotally attaching said support bracket to the other of said parallel stringers,

said aligning/spacing means of said kit comprising,

- c) an elongated member having a first element at each end thereof, said first element at one end of said elongated member cooperating with said engagement means of said support bracket and establishing a non-rotatively fixed positioning of said support bracket with said aligning/spacing means for distance and direction alignment and spacing of said support bracket with respect to an adjacent duplicate support bracket of a duplicate kit along said parallel stringers, and
- d) a second element integrally connected to said elongated member and extending laterally from a side surface of said elongated member, said second element extending beyond a side of said support bracket for insertion between said parallel stringers to establish a spacing and lateral positioning of said parallel stringers with respect to said support bracket and aligning/spacing means,

whereby said support bracket of said kit is adapted to be pivotally attached to said spaced parallel stringers, is adapted to be spaced from another support bracket of a duplicate kit by said first element of said aligning/ 10

spacing means, and adapted to be pivotally movable with parallel surfaces of said spaced parallel stringers.

- 2. The aligning/spacing means or the kit of claim 1 wherein said first element or said aligning/spacing means is adjustable to provide selectable spacing between said support bracket and an adjacent support bracket of a duplicate kit.
- 3. The riser/tread support bracket of the kit of claim 1 wherein:
 - a) said engagement means comprises a pair of alignment means being formed on opposite spaced end sides of said support bracket,
 - said pair of engagement means being in alignment across said support bracket parallel to said tread support surface.
- 4. The riser/tread support bracket of the kit of claim 3 wherein:
 - a) one of said pair of engagement means is a slot formed in said one of said spaced end sides,
 - b) and the other of said pair of engagement means is a notch formed in an opposite one of said spaced end sides.
- 5. The aligning/spacing means of the kit of claim ${\bf 1}$ wherein:
 - a) said aligning/spacing means is a bar,
 - b) said bar having said first element at each end of said bar for establishing said non-rotatively fixed positioning of said bar with respect to said reference surface of a support bracket,
 - c) said second element is a projection from a side surface of said bar integral with said first element for insertion between said parallel stringers to establish lateral spacing of said parallel stringers.

UNITED STATES PATENT AND TRADEMARK OFFICE CERTIFICATE OF CORRECTION

PATENT NO. : 6,354,403 B1 Page 1 of 1

APPLICATION NO.: 09/315809 DATED: March 12, 2002

INVENTOR(S) : Richard Truckner and Paul Truckner

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

IN THE ABSTRACT

LINE 3, "tred" should be --tread--

IN THE SPECIFICATION

COL. 5, lines 6, 9, 10, 11. 12, "banister" should be --ballister--

IN THE CLAIMS

COL. 10, lines 4 and 5, "or" should be --of--

Signed and Sealed this

Thirtieth Day of January, 2007

JON W. DUDAS
Director of the United States Patent and Trademark Office
